MEK6802D5

MICROCOMPUTER EVALUATION BOARD USER'S MANUAL

PREFACE

The MEK6802D5 Microcomputer Evaluation Board provides the necessary hardware and firmware for a computer system based on the Motorola MC6802 Microprocessor. The system forms an evaluation tool to faciliate the application of Motorola microprocessors and associated components. The system is supplied with all the components required to operate, including a 115 Vac plug-in transformer and integral power supply and can be used in various configurations. With the information supplied in this manual, the user can prototype dedicated systems plus write and evaluate software programs in machine language. Provisions are made for extensive system expansion using a video terminal or keyboard and CRT/TV display unit.

The information in this document has been carefully checked and is believed to be entirely reliable. However, no responsibility is assumed for inaccuracies. Furthermore, such information does not convey to the purchaser of this product any license under the patent rights of Motorola, Inc., or others.

Advance to next ADDR
Back-up to previous ADDR
Calculate offsets

Register Change/Display Breakpoint Editor

Cassette punch/load/verify Trace single instruction Go To/Continue user program User function capability

Escape from all functions

Save user registers

CHAPTER 1

GENERAL INFORMATION

1.1 Description

The MEK6802D5 Microcomputer Evaluation Board is a basic, low-cost system to evaluate the capability of the MC6800 Microcomputer Family of Components. It is useful as a tool to learn programming techniques, and to develop custom applications of microprocessors.

The system consists of an MC6802 microprocessor, D5BUG firmware in an MC68A316E ROM, (6) 7segment multiplexed displays, a 25-key scanned keypad, 300 Baud K.C. standard cassette interface and an on-board power supply capable of driving the minimum system.

A wire wrap area and an uncommitted user PIA are provided to allow the user to create desired options. In addition, provisions are made to add (2) MCM2114 $1K \times 4$ RAMs, a 24-pin ROM or EPROM, and Bus buffers to an 86-pin connector.

All components, including the AC transformer required for the minimum system are supplied with the MEK6802D5.

The functions of the basic and optional components of the system are described in the following sections.

1.2 Components

1.2.1 MC6802 - MPU (U5)

The microprocessor generates the system clock, executes the programs residing in D5BUG, and also executes user programs. There are 128 bytes of RAM (reserved for the user in the D5) included in the MC6802 (addresses \$0000 to \$007F).

1.2.2 MC68A316E - D5BUG (U12)

This factory programmed ROM (Read Only Memory), also known as a Monitor, contains the operating system firmware programs which control the D5 system.

1.2.3 MC6821 - PIA (U23)

This PIA (Peripheral Interface Adapter) is the system PIA and interfaces the keypad and display to the MPU. This unit can transmit data (in

parallel form) in either direction and provides a flow path for data in or out of the system. It also interfaces the cassette interface circuitry and trace-one instruction timer to the MPU (U5).

1.2.4 MC6821 - PIA (U9)

This PIA interfaces the D5 to external devices or systems for the user to use in producing custom designs. It provides two 8-bit bi-directional data ports and four control lines connected to a 24-pin Dip socket located adjacent to U9.

1.2.5 MC6810 - Static RAM (U11)

This is a static RAM (Random Access Memory) used as a scratch pad for the MPU (U5). It provides 128 bytes of Flag, Data, and Stack area for the D5BUG operating system (24 bytes are allowed for use as a user's stack area).

1.2.6 LED Display

The display system consists of LEDs, U15, U16, U17, U18, U20, U21; anode drivers Q1 through Q7; and cathode drivers U24 through U26. The system PIA (U23) uses seven lines to drive the anode drivers and six lines to drive the cathode drivers.

1.2.7 Keyboard

Depressing a key generates an interrupt to the processor. The system firmware causes the processor to search for the key closure and act upon it.

1.3 Optional Devices

1.3.1 MC2114 RAM Memories (U7, U8)

There are two 18 pin sockets for installing MCM2114 (1K \times 4 bit) static RAM memories.

1.3.2 Bus Drivers (U1, U2, U3, U10)

These units interface the processor to an 86 pin connector to expand the MEK6802D5 system.

CHAPTER 2

INSTALLATION

2.1 Preparation For Use

2.1.1 Handling

CAUTION

Turn power off before removing or installing components

SPECIAL HANDLING REQUIRED

Store board in special conductive bag. Do not touch circuitry while handling. Static discharge may damage components.

Generally, it is required that the board and repairing personnel all be at the same (ground) potential. If the unit is on a bench or is not installed, a common ground connection between installing and/or repairing personnel and the unit should be made.

2.2 Use

Place the D5 board on its stand offs or otherwise insulated from a bench or table top and plug the transformer into a wall outlet of the correct AC voltage. Refer to the operation section of this manual for more information.

2.3 Precautions

Because MOS devices have extremely high input resistance, they are susceptible to damage when exposed to high static electrical charges.

To avoid possible damage to the devices during handling, testing, or actual operation, use the following procedures:

a) The leads of devices should be in contact with a conductive material, except when being tested or in actual operation, to avoid build-up of static charge.

2.3 Precautions (cont'd)

- b) Soldering-iron tips, metal parts of fixtures and tools, and handling facilities should be grounded.
- c) Devices should not be inserted into or removed from circuits with the power on because transient voltages may cause permanent damage.
- d) Signals should not be applied to the inputs while the device power supply is off.
- e) All unused input leads must be connected to either V_{SS} (ground) or V_{DD} (device supply), whichever is appropriate for the logic circuit involved.

2.3.1 Handling of Unmounted Chips

In handling of unmounted chips, care should be taken to avoid differences in voltage potential. A conductive carrier, or a carrier having a conductive overlay should be used.

Some CMOS chips use a double diode plus resistor input protection circuit. This input protection circuit will clamp the input voltage to the chip to within the V_{DD} and V_{SS} supply voltages. This will protect the CMOS chip from over-voltages of 100 volts for 0.1 millisecond. The static charges encountered in normal handling may be as high as 10,000 volts.

2.4 Pin Assignments

Refer to Table 2.1 for the Bus Pinout Assignments for the MEK6802D5.

2.5 System Bus Signal Description

System Bus Signals:

- (1) 16 Address lines (AØ-A15) For selection of one byte or location from 64K bytes or locations.
- (2) 8 Data lines (DØ-D7) Bidirectional lines that carry data information.
- (3) 9 Control lines:
 - (a) E ENABLE. This signal is the system clock. A standard 3.579545 MHz crystal is used by the processor to generate the 894.8 KHz system clock.

TABLE 2.1. SYSTEM BUS PINOUTS

1	Pin Number	Description	Pin Number	Description
$ \begin{array}{c ccccccccccccccccccccccccccccccccccc$	7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42	+5 VDC +5 VDC HALT RESET R/W +12 V GND (ref) -12 V (ref) -12 V (ref) -12 V (ref) D1 D5 DØ D4 A15 A12 A11 A8 A7 A4 A3 AØ GND GND GND	A B C D E F H J K L M N P R S T U V W	+5 VDC +5 VDC 1RQ NMI VMA E (Ø2) +12 V GND (ref) -12 V (ref) BA MR +12 V (ref) D3 D7 D2 D6 A14 A13 A10 A9 A6 A5 A2 A1 GND GND

2.5 System Bus Signal Description (cont'd)

- (3) 9 Control lines (cont'd)
 - (b) R/\overline{W} Read/Write. This is the read-write control line. Its logic state determines the direction of data (into or out of) a selected chip. When high, the data direction is toward the processor (read), and when low, the data direction is away from the processor (write).
 - (c) VMA Valid Memory Address. When low this signal indicates that the address on the bus is invalid.
 - (d) MR Memory Ready. This control signal can cause the E signal to be stretched. When MR is high, E will be in normal operation. When MR is low, E may be stretched an integral multiple of half periods, thus allowing interface to slow devices.
 - (e) RESET. This line is used to reset and start the MPU.
 - (f) BA Bus Available. When this signal is active, the MC6802 is stopped and the address bus is available for external devices (but not tri-state).
 - (g) HALT. When this signal is active, all activity of the MC6802 will be halted.
 - (h) IRQ Interrupt Request. This signal requests than an interrupt sequence be generated within the MC6802. If the interrupt mask bit in the condition code register is set, the IRQ input is disabled.
 - (i) $\overline{\text{NMI}}$ Non-Maskable Interrupt. This signal is similar to IRQ except that the interrupt mask bit in the condition code register has no effect on NMI.

2.6 System Interfaces

2.6.1 Power

For the minimum system, an on-board power supply is provided which is driven by an 18 Vac center tapped transformer. Refer to Figure 2.1 (see page 2-5) in connecting the 18 Vac transformer.

If it is necessary to use an external supply for more power, just remove jumper E2 and connect the external supply as shown in Figure 2.2 (see page 2-5).

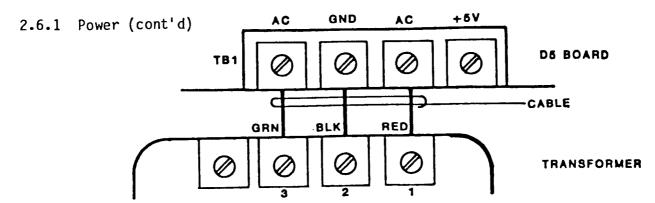

FIGURE 2.1. 18 VAC TRANSFORMER CONNECTION

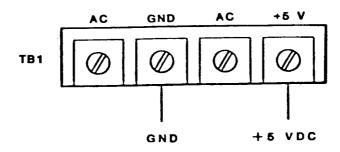

FIGURE 2.2. EXTERNAL SUPPLY CONNECTION

2.6.2 User PIA

A 40-pin socket has been provided to allow an additional uncommitted MC6821P in the D5. The PIA (U9) is supplied with the kit and the interface signals are available at the 24-pin socket (U14).

TABLE 2.2. USER PIA CONNECTOR PINOUTS

Pin		Pin	Description
Number	Description	Number	Description
1	PA6	13	GND
2	PA7	14	N.C.
3	PBØ	15	PA5
4	PB1	16	PA4
5	PB2	17	PA3
6	PB3	18	PA2
7	PB4	19	PA1
8	PB5	20	PAØ
9	PB6	21	CA2
10	PB7	22	CA1
11	CB1	23	N.C.
12	CB2	24	+5 V

2.6.2 User PIA (cont'd)

 $\overline{\text{NMI}}$ or $\overline{\text{IRQ}}$. Refer to the following figure while making connections.

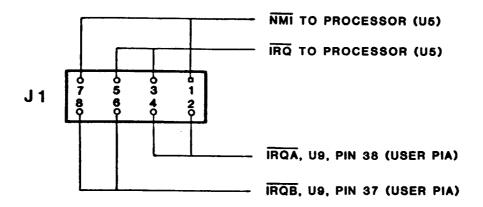

FIGURE 2.3. USER PIA INTERRUPT CONNECTIONS

The User PIA is decoded to appear at \$E480.

PORT A	\$E 480
DATA DIRECTION A	\$E480
CONTROL REG. A	\$E 481
PORT B	\$E482
DATA DIRECTION B	\$E 482
CONTROL REG. B	\$E483

2.6.3 Cassette

A 300 Baud Kansas City standard compatible cassette interface is provided for program storage. Most low-cost cassette recorders are compatible with the D5. The output from the cassette is connected to the "EAR" input at P3 of the D5. Generally the higher the cassette output level the better, but the D5 may accept as low as 2.0 Vpp.

To record programs connect the "MIC" output from P2 of the D5 to the "MIC" input to the cassette recorder. The D5 sends a 50 mVpp signal of 1200 Hz and 2400 Hz for zeroes and ones respectively.

2.7 Options

Several options are available for the user through installation or removal of various jumpers or components. In general, addition of options will require additional power which the on-board power supply may or may not be capable of supplying. The limiting factor in the on-board supply is the 7805 regulator heat dissipation characteristics. Some added power capability can be achieved by going to a TO-3 type regulator which can dissipate more heat. If the on-board regulator cannot supply enough power for the added options, then E2 may be removed to disconnect this regulator from the system allowing power to be supplied at the edge connector, or through the four (4) terminal barrier block TB1.

2.7.1 User RAM

Provisions have been made to allow addition of 1K x 8 of User RAM. This RAM is decoded to appear at addresses E000 - E3FF. To add this option install (2) MCM2114 1K x 4 RAMs at U7 and U8.

2.7.2 User ROM

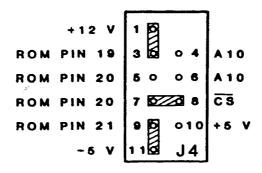

A 24-pin socket has been provided to allow the user to add an additional ROM with its own firmware. Decoding is provided to allow this ROM to appear at either of two areas in the memory map, \$E800 to \$EFFF or \$F800-\$FFFF. If the user wishes the ROM to contain the system restart and interrupt vectors, select the ROM at \$F800-\$FFFF and disable the monitor ROM from mirroring there. The user then has full access to all operating system routines but has priority during restart and interrupts. In addition to selecting where this ROM will appear, the user can connect the socket to accept various ROM or EPROM types. The following table outlines the proper connections for the most common EPROM types.

TABLE	2.3.	EPROM	CONNECTIONS

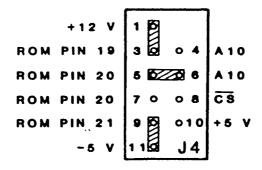

Types	Organ	nization	Pin 21	Pin 20	Pin 19	Pin 18
MCM270	6 2K	x 8	-5 V	CS	+12 V	GND
TMS271		x 8	-5 V	A10	+12 V	CS
MCM271		x 8	+5 V	CS	A10	GND

Refer to the following figures for configuring the ROM sockets as required. Figure 6.1, page 6-4 shows the location of these sockets.

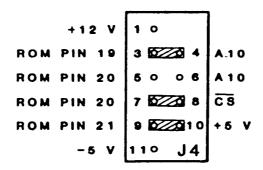

2.7.2 User ROM (cont'd)

a) Jumpers for 1K x 8, 3-supply EPROM.

b) Jumpers for 2K x 8, 3-supply EPROM.

c) Jumpers for 2K x 8 single supply EPROM.

FIGURE 2.4. CONFIGURING THE ROM SOCKET

2.7.2 User ROM (cont'd)

a) Option 1, select at \$E800 to \$EFFF.

b) Option 2, select at \$F800 to \$FFFF.

FIGURE 2.5. USER ROM OPTIONS

To use option 2 the system monitor mirror must be disabled by removing the jumper between pins 1-2 of J2.

2.8 Bus Expansion

To expand the D5 through the 86-pin connector, install (2) 74LS244 octal buffers at U1 and U2 and (1) 74LS245 octal bidirectional buffer at U3. Also install a jumper at E1 to disable the MC6802's internal RAM.

CHAPTER 3

OPERATION

3.1 Common Terms and Notations

Microprocessors are digital devices which understand 1 (ones) and \emptyset (zeroes). In the MC6802 there is a 16-bit address bus and an 8-bit data bus which communicate digitally (with binary 1's and 0's). It becomes cumbersome to specify 16-bit addresses and 8-bit data in binary 1's and 0's so a shorthand code called hexadecimal is used. Each hexadecimal digit (hex digit for short) represents (4) binary bits.

In order to distinguish hex digits from ordinary decimal numbers, precede the hex number with a dollar sign (\$). Sometimes it is very obvious that a number is a hex number and the "\$" symbol may be left off as in program listings. In a binary number, the leftmost bit is called the Most Significant Bit (\underline{MSB}) and the rightmost bit is called the Least Significant Bit (\underline{LSB}).

Any group of 8-bits is called a "byte" and a group of 4-bits may be called a "nibble". A "word" is a misleading term because many think it means 8-bits, but "word" really refers to the size of the data word.

In most microprocessors the data bus just happens to be 8-bits wide but there are exceptions such as the MC68000 which has a 16-bit "word" size.

Binary Nu	umber Hex	Representati	on
0000 0001 0010 0011 0100 0101		0 1 2 3 4 5	
0110		6 7	
0111 1000		8	
1001		9 A	Note: From 10 through 15 the
1010 1011		В	letters A through F are used for a single symbol to represent
1100		C D	the 4-bit binary number.
1101		E E	the 4-bit binary numbers
1110		F	
1111		I	

3.1 Common Terms and Notations (cont'd)

Since 7-segment displays are used on the D5, the hex values A through F are difficult to display. The letters \underline{B} and \underline{D} become lower case letters.

3.2 Display Indications

Step-by-step examples will show the resulting display. Notice there are 6 displays. In the examples a small letter x indicates "don't care"; that is it may not be possible to predict the actual value which will appear but it indicates that the display will not be dark.

3.3 Keypad Entries and Displays

Located at the end of this chapter are detailed examples which will help explain this section.

3.3.1 RESET

To reset the entire system, depress the "RS" button and the resulting display will be a dash in the left hand position.

3.3.2 ESCAPE

Normally it is possible to abort a user program by depressing the "EX" key; however, since this is dependent upon proper set-up of the keypad PIA, it is possible for the user's program to disable the ESCAPE function.

Assuming a user program and the ESCAPE function active at the time the "EX" key is depressed, the resulting display would reflect the current user Program Counter status and the system would be in the register display editor.

If the system was within the DEBUG operating system when "EX" was depressed the resulting display would be a dash in the left hand position.

3.3.3 Miscellaneous

While entering numeric information, the first digit entry will clear the entire register location being modified and the new digit will be rotated into the least significant 4 bits of the register. Subsequent entries will be shifted in from the right and there is no limit to the number of digits which may be entered. When the next command key is depressed, the value being displayed is the value which will be used.

3.3.3 Miscellaneous (cont'd)

When trying to GO to a user program, a check is performed to see that the user's system stack can support the process of exiting to the program. The method used to transfer control to the user program requires that the user's register contents be put on the system stack and, if no RAM exists at the "S" stack pointer location, then control cannot be passed to the program. The display will be -SP- ??.

3.3.4 Memory Display/Change

To display or change the contents of a memory location, first enter the hexadecimal address to be changed. Leading zeroes are not required and digits may be entered until the display is correct. When this address has been entered, depress the "M" key.

The first four display digits show the address of the memory location being operated on. The fifth and sixth displays show the actual contents of the displayed address and if they do not agree with the data entered, it is an indication that the location is not properly accepting data.

To advance to the next higher memory location, depress "GO" and to backup to the next previous location, depress the "M" key.

3.3.5 Offset Calculation

To calculate a relative offset, depress "FS" from the memory display change editor. The memory location being displayed at the time the "FS" key was depressed is assumed to be the location of the offset byte. The display at this point will be an A in the right most position,

prompting an entry of the destination address. After this address has been entered, depress "GO". The offset will be calculated and checked to see if it is within the range of an 8-bit offset. The resulting display will be two numbers in the right most two displays or the letters BAD indicating the offset was out of range. The numbers are an 8-bit offset value.

Note this offset on the listing before continuing.

Depress "GO". The calculated offset is stored and control returned to the memory display/change editor. The memory location being displayed will be that immediately following the offset which was just stored.

3.3.5 Offset Calculation (cont'd)

If, for some reason, the calculated value should not be stored prior to continuing, depress the "FC" key which will return control to the memory display/change routine. The displayed memory location will be the same one from which the offset calculation routine was called.

If the calcuation was "BAD" depressing "M" will return to the memory change editor.

3.3.6 Register Display/Alter

To get to register display, begin at the prompt point and depress "RD". The first register displayed will be the user's program counter.

3.3.7 Summary of Register Display Formats

ı——				i		<u> </u>	1
рс	рс	рс	рс		Р	С	User program counter
		a	a			Α	User A - register
		b	b			Ь	User B - register
x	Х	Х	x		I	d	User X index register
sp	sp	sp	sp		S	Р	User stack pointer
		С	С		С	С	User condition codes

To advance to the next sequential register depress the "GO" key and to back up to the next previous register depress the "M" key. The registers "wrap-around" so depressing "GO" while displaying CC, the next display will be PC.

To change the contents of a psuedo register, just step to that display and enter the desired value.

3.3.8 Trace Single Step

To trace a single MC6802 instruction, just depress "T/B" from within the register display editor. After executing a single user instruction, the operating system will regain control in the register display editor and all registers will reflect the action of the executed instruction. Depress "T/B" as many times as desired to execute that many instructions.

3.3.9 Go To User Program

To Go to a user program, start at the prompt point (a dash in the left most display). Enter the address desired and then depress "GO".

3.3.10 Continue

1

This is like GO to user program except instead of specifying the GO address, it is assumed to be the current value at the user program counter pseudo register. To invoke this function, depress "GO" from the "-" prompt point. It should not be necessary to enter any numbers prior to "GO" to invoke the "CONTINUE" function.

3.3.11 Breakpoints

To enter the breakpoint editor, depress "FS" then "T/B" from the prompt point.

To get out of the breakpoint editor, depress the "EX" key. To advance to another breakpoint specification, depress "GO". The advance function wraps around so successive presses of "GO" will eventually display all breakpoints. Up to 5 breakpoints may be active at any time.

To de-activate an existing breakpoint, advance to where it is being displayed and depress "FC". The last digit of the display (# of breakpoints) will decrement and another breakpoint will be displayed. To remove all breakpoints, depress "FC" as many times as needed until the "# of breakpoints" digit is zero.

To install a new breakpoint, enter its proposed hexadecimal address, then depress "FS". Breakpoints will only be installed where there is a RAM. If the "# of breakpoints" digit does not change, it is an indication that the breakpoint could not be installed either because five breakpoints already exist or because the breakpoint code (\$3F) could not be stored at the proposed address.

3.3.12 Punch

To punch a cassette tape, begin from the prompt (-) point. Depress "P/L" and the display will be 0000 bb, prompting for a beginning address.

For example, depress 1, 2, 3. The display will be 0123 bb.

Depress GO to enter this address. The display will now be 0000 EE, as a prompt to enter the last address of the data to be punched.

For example, depress 4, 5, 6, 7. The display will be 4567 EE.

3.3.12 Punch (cont'd)

Turn on the tape recorder in the RECORD mode and depress GO. A 30 second leader of \$FF characters will preced the data file.

When the punch process is complete, the prompt (-) returns and the D5 board is ready for the next command.

3.3.13 Load/Verify

The load command is "FS" then "P/L" while the verify command is "FS" - "RD".

When the load or verify is completed without errors, the prompt returns and the D5 is ready for the next command.

If an error occurred during load or verify, the message "Fail ??" appears on the display. The user may escape at this point and enter register display to find the error location. The address in error is indicated by the value in the X-register. Also the data in the A-register is the last byte read from the tape.

3.3.14 User Functions

User functions may be performed by use of the function set key and the user function pointer (FNCPNT).

User functions are invoked by typing "FS" and a hex digit.

User functions are set up by providing a table of addresses of user supplied functions, and by storing the address of the table at FNCPNT

Up to 16 functions may be added to the functions already on the D5.

Display and Programming Examples

These examples are given to illustrate programming techniques and applications using the MEK6802D5.

Example to display 'USE d5'

1. Determine the necessary 7-segment display codes required for the letters and numbers to be displayed. This information is found in the detailed description of the "PUT" routine in Chapter 7.

Symbol Symbol		Bina	Hex		
		0011	1110		* 0 =
U	=	0011	1110	=	\$3E
S	=	0110	1101	=	\$6D
Ε	=	0111	1001	=	\$79
space	=	0000	0000	=	\$00
ď	=	0101	1110	=	\$5E
5	=	0110	1101	=	\$6D

- 2. Each symbol is listed with its binary equivalent and hex code keypad entry.
- 3. The program listing entries are explained in the D5BUG listing (Chapter 7). The complete program listing for this example is as follows (next page):

After entering this program into memory using Memory Change, press $"\emptyset"$ and "GO" to begin execution.

Display and Programming Examples (cont'd)

Example to display 'HELP --'

1. Determine the 7-segment codes required, as in the previous example.

Symbol		Binar	Hex		
Н	=	0111	0110	=	\$76
Ε	=	0111	1001	=	\$79
L	=	0011	1000	=	\$3 8
Р	=	0111	0011	=	\$73
_	=	0100	0000	=	\$40
_	=	0100	0000	=	\$40

- 2. Each symbol is listed with its binary and hex codes equivalent.
- 3. The program listing entries are explained in the D5BUG listing (Chapter 7). The complete program listing for this example is as follows (next page):

HELP

0001						NAM	HELP

After entering this program into memory using Memory Change, press "0" and "G0" to begin execution.

Display and Programming Examples (cont'd)

To help in better understanding the $\underline{\text{PUT/MNPTR}}$ routine operation, try the following:

DIDDLE has been used so far as the subroutine which is executed once each millisecond from PUT. Now substitute a long delay using the DLYX routine as the subroutine which is specified by MNPTR.

0020	CE	FFFF	SLOW	LDX	#\$FFFF	For 1/2 second delay
0023	BD	F179		JSR	DLYX	Delay
0026	39			RTS		Then return to PUT

To install SLOW as the active subprogram of PUT, just change the third last step of the "HELP --" program:

was:

0012 CE FOA2 LDX #DIDDLE Addr of DIDDLE routine

to:

0012 CE 0020 LDX #SLOW Addr of SLOW routine

When the program is running between successive digits (which are on for about 1 millisecond) there is an approximately half second delay.

Adjust the amount of delay by changing FFFF at 0021,2 and observe the effect.

This example is a clock program to display time in a 24-hour format. The program is as follows (next page):

TIME

```
0001
                                NAM

After entering this program into memory using Memory Change, press "5" and "GO" to begin execution.

Comments on 24 hour clock program "TIME"

The technique used to measure time is called "software timing" and relies on the system clock accuracy and the sum of the execution times on all of the instructions being performed. This is a cumbersome technique to do right.

Determine all the different paths through the program in order to accurately predict the program's total execution time.

This is precisely the technique used in some digital watches, but in that case there is a fine adjustment to tune the clock frequency to better than .001% which comes out to about 5 minutes per year. In a typical microprocessor system, the clock speed is not adjustable and accuracy is about 0.1% which comes out to more than a minute a day.

As for calculating actual program execution time, look at the program to see how many different paths there are <u>just</u> from the label "TIME" to "TBOT":

- 1. Not end of tick.
- 2. End of tick, not end of minute, not a tenth second.
- 3. End of tick, not end of minute, second tens digit incr.
- 4. End of tick, end of minute, not end of hour, not a tenth minute.
- 5. End tick, end minute, not end hour, minute tens digit incr.
- 6. End tick, end minute, end hour, not end day, not a tenth hour.
- 7. End tick, end minute, end hour, end day.

Each of the above paths through the TIME program takes a different length of time because a different sequence of instrucitons is followed. That's just part of the task; to completely calculate the execution time, do the same thing to every routine being executed. Then to find the total, determine exactly how many times each path is followed and add up all those times.

CHAPTER 4

THEORY OF OPERATION

4.1 General

The MEK6802D5 allows the user to become familiar with the MC6800 family of microprocessors. Refer to the block diagram, Figure 4.1, and the component function location diagram, Figure 4.2.

The three basic components of the D5 are (1) U5, the MC6802 microprocessor, (2) U12, the MC68A1316E ROM, and (3) U23, the MC6821 PIA.

The MC6802 is the heart of the D5 system. The MC6802 is an eight (8)-bit microprocessor that can execute 72 different instructions (exact instruction set of the MC6800). Included are binary and decimal arithmetic, logical, shift, rotate, load, store, conditional or unconditional branch, interrupt and stack manipulation instructions.

The MC6802 has a set of registers and accumulators plus an internal clock oscillator and driver.

For a more detailed explanation and description of the MC6802 Microprocessor refer to the data sheet located at the end of this manual.

The MEK6802D5 utilizes a 3.58 MHz crystal (Y1) to control this circuitry (this results in a system operating speed of 895 KHz). Power on/reset is accomplished by components R1 and C17.

Basic to the operation of the D5 system is the Data bus (eight lines labeled BDØ through BD7) and the Address bus (sixteen lines labeled BAØ through BA15). These buses interconnect to the various sections.

The address bus is further decoded by the Address Decode Logic (U6) into select lines. J2 and J3 must be set properly to accomplish this. These jumpers are specified in the installation section of this manual for the various board arrangements possible.

The ROM section is the permanent data storage. Unlike some types of memories, this ROM retains data whether the power is on or not.

The ROM section consists of the D5BUG Monitor (U12) and the optional User ROM (U13). J4 is used to configure the user ROM socket to accept various types of ROMs or EPROMs. J2 is used to position U13 (user ROM) in memory space. J3 is used to position U12 (D5BUG) in memory space.

The RAM section consists of a 128 byte static Random Access Memory. This memory will retain its stored data as long as power is supplied to it and can be written into and read out of as desired.

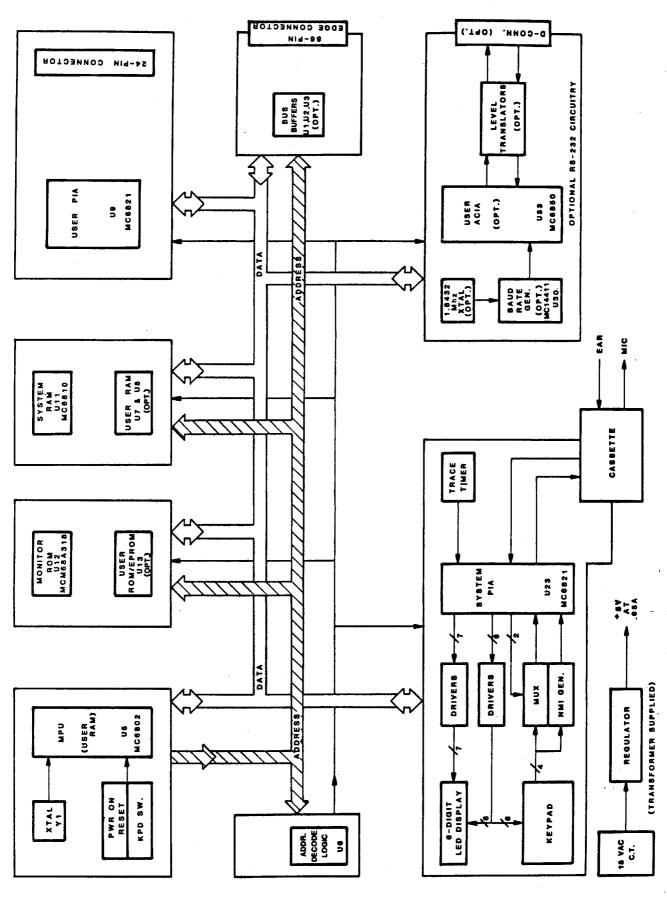

FIGURE 4.1. BLOCK DIAGRAM

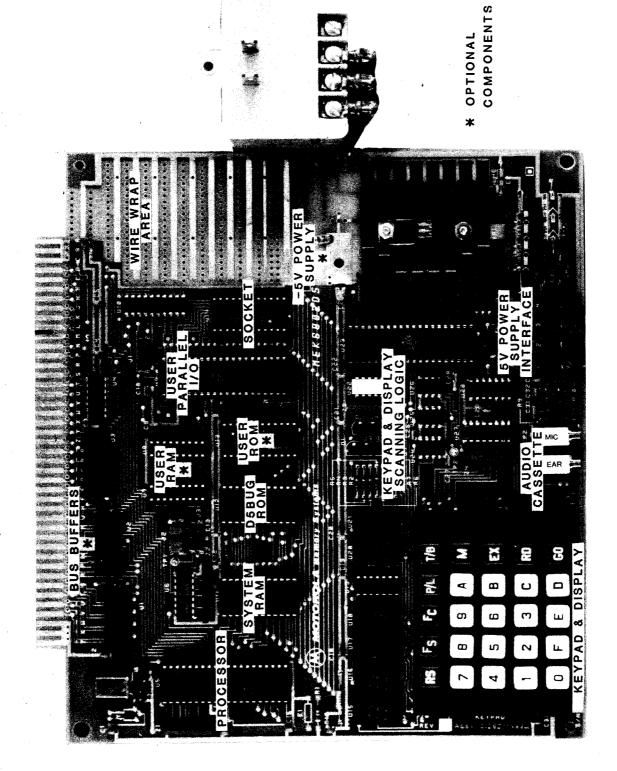

FIGURE 4.2. COMPONENT FUNCTION LOCATION DIAGRAM

The D5 uses this RAM as a Scratch Pad, which is a temporary storage for program material being processed. An example of this could be a program that uses a set of data a large number of times during the running of the whole program. This device would allow that data to be referred to as needed, rather than being repeated over again in the main program.

Another optional feature is the User RAM (U7 and U8). This provides the user with an additional (1K) bytes of memory. This feature is valuable when long programs must be stored.

These memories are volatile, and power must be supplied to them to retain their stored data.

The system PIA has two 8-line I/O ports and four control I/O lines for a total of 20 interface lines. The four control lines provide for a variety of hand shake applications. The two I/O ports are controlled by software to configure these 16 lines as inputs or outputs in any combination.

The User PIA (U9), allows the processor to talk to the outside world. Th $16~\rm{I/O}$ lines and 4 control lines are connected to a 24-pin socket (U14).

The optional Bus Buffers (U1, U2, U3) are for expanding the D5 through an 86-pin edge connector. This is accomplished by plugging an IC in the supplied sockets. Note that U10, also a bus driver, is part of the basic D5 since the processor's R/W output cannot drive all the inputs in the basic system (or the bus). All the control signals, data, and addresses are available on this bus for system expansion.

The system PIA, (U23) uses its A side to drive the anode segments of the LED displays and the B side to drive the LED cathodes. The processor put data into the register of the PIA to display on one of the LED's, then places data in the PIA registers to drive the next display element, etc., at a rapid enough rate that the display appears steady.

The keypad is connected to the cathode drivers of the LED's so that when a key is depressed, an interrupt signal is generated. This interrupt signal causes the processor to call up a routine from D5BUG, which then enables it to search for the key that was closed. The PIA is used to enter new data or display data in the system.

The D5 can be supplied to interface to the widely used RS-232 bus. An Asynchronous Communications Interface Adapter (ACIA) converts the parallel data on the data bus to a serial form suitable for transmission

4.1 General (cont'd)

over a communications system. This ACIA will both transmit and receive data and allows the D5 to be used as a remotely controlled processor. An MC14411 Bit Rate Generator supplies the special frequency that the ACIA requires in making the conversion from parallel to serial data.

An installed jumper determines the frequency of data formatted in serial form. A socket allows cabling to the RS-232 line.

4.2 Addressing

The MEK6802D5 accesses 64K of memory space by use of 16 address lines AØ through A15. The addresses \$EØØØ to \$FFFF access parts on the MEK6802D5 and external data buffers are not enabled for such accesses. The area from \$ØØØØ to \$ØØ7F is RAM within the MC6802 and must be disabled by jumper option if the optional bus buffers are installed.

When the optional edge connector bus buffers are installed, all accesses to addresses \$9000 to \$DFFF are considered to be off-board.

The system memory map is shown in Figure 4.3, the Address Decode Map in Table 4.1 and the System Timing Diagram in Figure 4.4.

Test Conditions:

- 1) Operating temperature, TA = 25°C.
- 2) Timing signals measured at I/O connector (50% points).
- 3) I/O loading conditions equivalent to 74LS type devices.
- 4) Measured from the rising edge of E (\emptyset 2).
- 5) Measured from the falling edge of E (\emptyset 2).

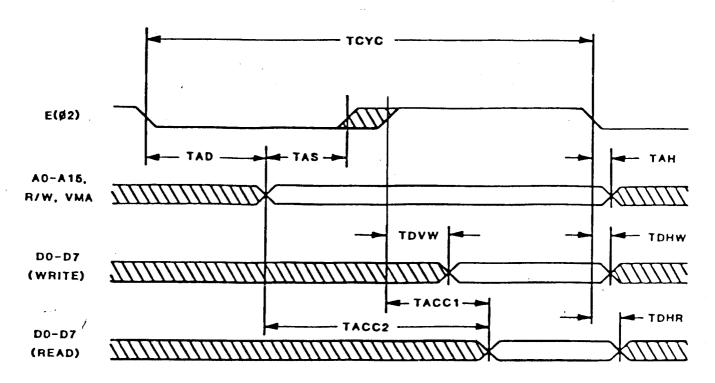

FIGURE 4.4. SYSTEM TIMING DIAGRAM

CHAPTER 5

MAINTENANCE

5.1 Troubleshooting

Troubleshooting techniques can be divided into several steps:

- a) Check and analyze operation.
- b) Test to isolate section, stage, and part.
- c) Replace the defective part.
- d) Performance test after repair.

For all troubleshooting, refer to the system schematic, Figure 5.1, and to the component location diagram, Figure 6.1, in Chapter 6.

Begin troubleshooting by checking the power supply voltages used with the D5. Check for secure and correct transformer connections.

The 86-pin edge connector fingers are tin lead plated and should be cleaned for reliable operation.

Use caution when replacing defective parts. Improper handling (refer to Chapter 2) and too much heat can destroy components.

5.2 Standard Logic Symbols

5.2.1 Digital Logic Circuits

All digital equipment, simple or complex, is constructed from a few basic devices. These devices consist of electronic circuitry that provides an output based on the input of one, two, or more variables and are called logic elements (most often referred to as gates).

Digital logic circuits are broken into two basic types: decision-making and memory elements. All decision logic elements monitor binary inputs and produce outputs based on the input states and the operational characteristics of the logic element. Memory elements are used to store binary data. Table 5.1 gives the basic logic elements, their more commonly used forms, and their single binary output. All other digital logic elements and circuits are variations or combinations of these basic elements.

TABLE 5.1. LOGIC SYMBOLS AND TRUTH TABLES

		Tru	ith Table	*
Device	Logic Symbol	Α	В	χ
INVERTER	A ————————————————————————————————————	L H		H L
AND	Ах	L H L H	L H H	L L H
UR	^х			L H H
NAND	А ————————————————————————————————————	L H L	L H H	H H L
NOR	AX	L H L	L L H	H L L
XOR (EXCLUSIVE OR)	А	L H L H	L L H	L H H L

^{*} The Truth Table is a table showing all possible combinations of inputs with the respective output for each set of inputs.

H = High voltage (logic 1)
L = Low voltage (logic 0)

CHAPTER 7

SOFTWARE LISTING AND DESCRIPTIONS

7.1 General

This chapter consists of the subroutine descriptions, the D5BUG software listing, and other useful information for the MEK6802D5.

7.2 Subroutine Descriptions

7.2.1 RESET

(\$F000)

Routine:

Hardware Reset (cold start)

Descripton:

Sets interrupt mask

Clears all RAM from \$E400-E47F

Initializes system PIA

Establishes default user stack pointer (\$E418)

Passes control to PROMPT routine

7.2.2 PROMPT

(\$F024)

Routine:

Software Reset (warm start)

Description:

Initializes system stack pointer (\$E47E)

Sets-up software flags:

ROLPAS = 1 UPROG = 0 ROIFLG = 0 KYFLG = 0 FNCFL = 0

Clears 7 -Seg displays
Displays prompt symbol (-)

Establishes FUNSEL as active main program

7.2.3 GET

(\$F04E)

Routine:

Subroutine to read, decode, and debounce a keypad

switch.

Effects:

All registers are altered by this routine. The A-

register has the key code in it on return.

RAM location KYFLG will have \$01 in it on return and the code of the key that was depressed will be

in location KEY.

7.2.3 GET (cont'd)

Routines Called:

DLY25

MMINT

Stack Requirement:

4 bytes.

Description:

The keys of the keypad are electrically arranged into 6 rows and 4 columns. The "RS" (reset) key is not part of this row/column arrangement. GET is called when a key is depressed and the return does not take place until about 25 milliseconds after the key is released. While the key is closed, GET searches the matrix to find the key's row then its column. The Row/Column information is used to address a look-up table from which a key code value is fetched.

This code is stored to the RAM location KEY and is also in the A-register when GET returns. A RAM location called KYFLG is set to \$01 to indicate that a key was entered, when another routine recognizes this flag, it should read the KEY code and clear KYFLG, to acknowledge that the key was seen.

Normally the GET routine is serviced through an NMI which results when any key is closed but the interrupt output of the KPD PIA could be disabled allowing GET to work on a polled basis. Polling means that periodically the PIA's control register is read ("Polled") to see if a key was depressed since the last time the program looked.

Calling Routines:

KEY CODE SUMMARY

K	EY CODE S	SUMMARY

FIGURE 7.1. KEY CODE AND FUNCTION SUMMARY

7.2.4 PUT

(\$FOBB)

Routine:

Utility program to display information on the 7-segment displays and call the active main program as a subroutine once each millisecond.

Effects:

The A, B, and X-registers are altered by PUT.

Routines Called:

DLY1, routine specified by MNPTR.

Stack Requirement:

1 in addition to main program requirement (Minimum-3 bytes total).

Description:

The PUT routine is the heart of the operating system because the displays must be continuously scanned. Anode information for the desired display is presented to the parallel anode lines and the appropriate cathode is driven turning on the proper segments. A given digit is turned on for about one millisecond then the cathode is disabled, the anode information changed to that of the next digit, and the next cathode is enabled.

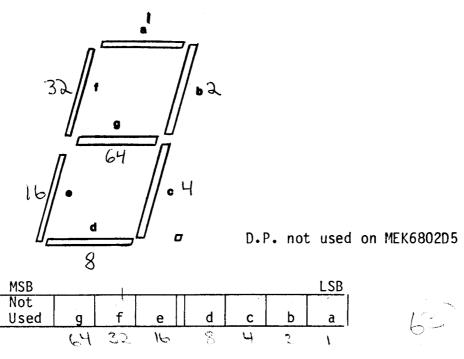

During the short period between digits a subroutine who's address is stored at RAM location MNPTR is executed. Upon RESET or PROMPT, MNPTR is set to the address of the function select routine (FUNSEL). When FUNSEL wishes to pass control to some other routine, it stores the address of that routine at MNPTR which 'activates' the new routine (and de-activates FUNSEL).

Another way of putting this is to say that the display routine calls 'some program' once per millisecond and 'some program' is the program whose address is stored at RAM location MNPTR.

The PUT routine obtains the segment information from a 6-byte buffer called DISBUF, which contains 7-segment data for the displays with the first byte corresponding to the leftmost display. In addition the B-register keeps track of which digit is to be enabled with the third-from-the-left bit corresponding to the leftmost display and the LSB corresponding to the rightmost display.

ŧ

NOTICE: The anode interface drivers are ground true so the PUT routine inverts the data in DISBUF before it is stored to the hardware so that the data in DISBUF will be high true.

7-segment bit relationship to display

EXAMPLE: To display the character "F" the data in DISBUF would be:

a - 1 b - 0 c - 0 d - 0

e - 1 f - 1

g - 1

Not

Used - don't care; make 0

01110001 or \$71

FIGURE 7.2. CHARACTER DISPLAY

7.2.5 DYSCOD

(\$F120)

Routine:

Convert hexadecimal data from HEXBUF into 7-segment

codes and store in DISBUF.

Effects:

The contents of the A, B, and X-registers are saved

and restored prior to returning from DYSCOD.

On return the RAM locations DISBUF through DISBUF+5 contain the 7-segment codes for the hexadecimal

information in HEXBUF through HEXBUF+2.

Routines Called:

ADDAX

Stack Requirement:

9 bytes.

Description:

The six nibbles of hexadecimal information from

HEXBUF through HEXBUF+2 are each converted to a byte of 7-segment anode information which is stored in the six byte display buffer (DISBUF). The most significant 4 bits of location HEXBUF correspond to the location DISBUF and the least significant 4 bits of HEXBUF+2 correspond to the location DISBUF+5.

The resulting 7-segment information is displayed on the D5's six LED displays by the PUT routine. The first byte of DISBUF corresponds to the leftmost display and the sixth byte (DISBUF+5) corresponds

to the rightmost display.

7.2.6 DLY25, DLY1, DLYX

(\$F169) (\$F171) (\$F179)

Routine:

These routines cause delays of 25 milliseconds, one (1) millisecond, or a variable delay based on the

value in the X-register.

Effects:

The contents of the X-register are saved and restored prior to returning from the routines. The A and B-registers are not altered by the delay routines.

Stack Requirement: 2 bytes.

Description:

Calling DLY25 or DLY1 will cause an execution time

delay of about 25 milliseconds or 1 millisecond respectively. Calling DLYX will cause a delay based on the value in the X-register according to the

following formula:

[(X-1) (8 cyc) (1.11763 us/cyc)] + (27.94 us)

7.2.6 DLY25, DLY1, DLYX (cont'd)

A minimum delay of 27.94 us results from an X-register value of 1 (\$0001) and a maximum delay of 0.5842 seconds results from an X-register value of 0 (\$0000 - 1 = \$FFFF = 65,535).

7.2.7 ADDAX

(\$F183)

Routine:

Add A-register to X-register.

Effects:

A and X-registers altered by ADDAX.

Stack Requirement:

2 bytes.

Description:

The value in the A-register is added to the value in the X-register and the result is returned in

the X-register.

7.2.8 CLRDS

(\$F195)

Routine:

Clear LED display digits per a mask in the A-register.

Effects:

The A-register is altered by CLRDS.

The contents of the X-register are saved and re-

stored prior to returning from CLRDS.

Stack Requirement:

2 bytes.

Description:

Each of the low order six bits of the A-register correspond to one of the D5's LED displays with the LSB of the A-register corresponding to the rightmost display. For each bit that is a logic 1, the corresponding display buffer location will be cleared result-

ing in that display goind dark.

Example:

0011 1100 (\$3C) would clear the first four LED dis-

plays.

7.2.9 ROLL2

(\$F1AA)

Routine:

Numeric entry routine for 2-digit (1-byte) values.

Requirements:

Least significant 4-bits of A-register contain the new hexidecimal digit and the most significant 4-

bits must be cleared.

7.2.9 ROLL2 (cont'd)

ROLPAS flag (when set) indicates "first pass" which results in the location being cleared prior to rolling the new digit in from right.

Tring the new digital in it am t

Effects: A-register altered by ROLL2, X-register contents

saved and restored prior to return from ROLL2.

Stack Requirement: 2 bytes.

Description: The address of the location to be operated on by

ROLL2 is specified in HEXBUF and HEXBUF+1. A new hex digit is passed to ROLL2 in the least significant 4-bits of the A-register. This new digit is shifted in from the right so that the digit which was in the least significant 4-bits of the location is now in the most significant 4-bits. The digit which was in

the most significant 4-bits is lost.

If the flag ROLPAS was not equal to zero, then the location is cleared before the new digit is rolled in. ROLPAS is cleared to signal it is no longer the first

pass.

7.2.10 ROLL4 (\$F1CC)

Routine: Numeric entry routine for 4-digit (2-byte) values.

Requirements: ROLPAS flag (when set) indicates "first pass" which results in the locatins HEXBUF and HEXBUF+1 being

cleared prior to rolling the new digit in from the

right.

The least significant 4-bits of the A-register contains the new digit and the most significant 4-bits

of the A-register must be cleared.

Effects: A-register is altered by ROLL4, B-register is

saved and restored prior to returning from ROLL4.

Stack Requirement: 3 bytes.

Description: The locations into which ROLL4 shifts the new digit

are HEXBUF and HEXBUF+1. The new digit is passed to ROLL4 in the least significant 4-bits of the A-register. This new digit is shifted into the first two bytes of HEXBUF such that the new digit ends up in the least significant 4-bits of HEXBUF+1. What was in the low 4-bits ends up in the high 4-bits of HEXBUF+1 and what was in the high 4-bits of HEXBUF+1

7.2.10 ROLL4 (cont'd)

ends up in the low 4-bits of HEXBUF. What was in the low 4-bits of HEXBUF ends up in the high 4-bits of HEXBUF, and what was in the high 4-bits of HEXBUF is lost.

If the ROLPAS flag was not equal to zero then HEXBUF and HEXBUF+1 will be cleared prior to shifting in the new digit, and ROLPAS will be cleared to indicate no longer first pass.

7.2.11 RDKEY

(\$F1EF)

Routine:

Read and acknowledge a keypad key.

Requirements:

Normally RDKEY would be called because KYFLG was set indicating that a key had been depressed.

Effects:

KEY value returned in A-register.

KYFLG cleared to acknowledge that the key has been recognized.

Stack Requirement:

2 bytes.

Description:

Load the key code from KEY into the A-register and clear KYFLG to acknowledge that the key has been recognized.

7.2.12 TIN

(\$F533)

Routine:

Read 1 byte of data from tape.

Effects:

The A and B-register contents are altered by TIN.

On return the location BYTE (\$E459) contains the character that was recovered from tape. register also contains the recovered data.

FEDGE

Routines Called:

Stack Requirement:

4 Bytes.

Description:

TIN is used to read 1 Kansas City standard format character from cassette tape. The character format is:

a) Logic Ø Bit-Time = 4 cycles of 1200 Hz.

7.2.12 TIN (cont'd)

- b) Logic 1 Bit-Time = 8 cycles of 2400 Hz.
- c) Characters consist of:
 - i) 1 Logic Ø Bit-Time as a "Start" bit.
 - ii) 8 Data Bit-Times (LSB first).
 - iii) At least 2 logic 1 Bit-Times as "Stop" Bits.

Software timing techniques are used and an error tolerant algorithm is employed to assure reliable data recovery. The TIN routine is in control from before a start bit until just after the eighth data bit in the serial stream.

During the stop bit-times the previous data character is processed by other software. At the 300 Baud data rate the stop bits take 13.3 milliseconds.

When reading successive data characters, the software which processes the previous byte read must finish in time to call TIN at least one full cycle before the next start bit-time. This will allow TIN to regain synchronization with the serial data stream.

The time required from the last cycle of the instruction that calls TIN until the first test for an edge is exactly 47 processor cycles or 52.5 microseconds.

The time from the end of the last cycle of the last data bit-time until the completion of TIN's RTS instruction is 100 cycles or 111.2 microseconds.

Generally it will be easy to process the previous character in time to get back to TIN for the succeeding character.

7.2.13 PNCHB

(\$F608)

Routine:

Format and send one byte of data to the tape interface.

Effects:

The contents of the A and B-registers are altered during PNCHB.

Routines Called:

BITØ, BIT1, INVRT.

Stack Requirement: 6 bytes.

7.2.13 PNCHB (cont'd)

Description:

Refer to the description of TIN for the format of tape characters.

Software timing techniques are used to create a serial stream of cycles of the proper duration to form Kansas City Standard audio signals.

When punching consecutive bytes of data it is vital to maintain timing control between successive bytes, not just within the character.

PNCHB consumes exactly 35 MPU cycles from the last MPU cycle of the calling instruction until the first start bit edge is sent. Timing is then automatically controlled by PNCHB while the character is being transmitted.

After transmitting the second last edge of the last stop bit PNCHB returns. The edge which marks the completion of the last stop bit cycle also marks the beginning of the succeeding start bit for the next character. It is supplied as the first edge transmitted by the next call to PNCHB.

The time allowed from the last cycle of PNCHB's RTS until the next edge must be transmitted is exactly 159 MPU cycles.

159 minus the 35 for entry to PNCHB the next time leaves exactly 124 cycles which must be consumed by external software. For example, if it takes 50 cycles to set up for the next character, the remaining 74 (124-50) cycles must be consummed in dummy delays before calling PNCHB again.

7.2.14 PUNCH

(\$F630)

Routine:

Format and punch an entire file to the cassette.

Effects:

The A, B, and X-register contents are altered during

PUNCH.

Routines Called:

PNCHB

Stack Requirement: 8 Bytes.

Description:

PUNCH is a time-tuned subroutine.

7.2.14 PUNCH (cont'd)

Before calling PUNCH store the beginning address of the data to be punched at RAM location BEGAD (\$E460,1) and the ending address at ENDAD (\$E462,3).

The file format is as follows:

- 30 seconds of \$FF characters as leader.
- Block start character "S" (\$53). b)
- Begin address high byte. c)
- d) Begin address low byte.
- e) End address high byte.
- End address low byte. f)
- Data in binary form starting with data at Begin address to and including data at End address.
- One byte checksum. Checksum is the two's complement summation of all data bytes plus the begin and end address characters. When loading, the simple sum of all data in the file starting with the first byte of the begin address and including the checksum character should be zero.

7.2.15 LOAD

(\$F69C)

Routine:

Load or verify a D5 format tape file to memory from

cassette.

Effects:

The A, B, and X-register contents are altered by

LOAD.

Routines Called:

TIN.

Stack Requirement:

6 bytes.

Description:

The LOAD routine is used to read a tape data file into memory or verify a tape file against the contents of memory. If the least significant bit of the flag FNCFL (\$E43E) is set, a load takes place, otherwise a verify is performed.

Normally if a checksum error is detected, an error message is displayed on the 7-segment LED's.

This may be overriden by setting the MSB of FNCFL (\$E43E) prior to calling LOAD. When the override feature is used, the Z condition code may be checked upon return from LOAD to determine if the load was acceptable. If Z is true the load was good.

GENERAL NOTE FOR CASSETTE ROUTINES

The cassette routines rely on critical execution time-tuning to work properly.

To use the individual routines outside the context of the D5BUG operating system, take care to abide by the timing requirements of the individual routines.

To assist in this effort, the number of processor cycles required by each instruction is presented as the first character(s) in the comment portion of each listing line for those routines.

7.3 Program Address Descriptions

TABLE 7.1. D5BUG USEFUL PROGRAM ADDRESSES (Also Refer To Complete D5BUG Listing)

Name of	T	
Routine	ADDR in D5BUG	Description
RESET	\$F000	Cold Restart
PROMPT	\$F024	Warm Start
GET	\$F04E	Routine to Read a Key (Uses NMI routine so a user would not normally use this routine directly.
PUT	\$FOBB	Display Data on 7-segment readouts and calls functioning subroutines.
DYSCOD	\$F120	Decode Hex to 7-segment.
DLY25	\$F169	Delay 25 milliseconds.
DLY1	\$F171	Delay 1 millisecond.
DLYX	\$F179	Delay based on X-Reg (about 1/2 second Max).
ADDAX	\$F183	Add A-Register to X-Register.
CLRDS	\$F195	Clear display digits per A-Register mask.
ROLL2	\$F1AA	Numeric entry routine for 2-digit values (one byte). Address being operated on specified in "HEXBUF".
ROLL4	\$F1CC	Numeric entry routine for 4-digit values (2-Bytes).
RDKEY	\$F1EF	Read and acknowledge key.
TIN*	\$F533	Read 1 byte from tape.
PNCHB*	\$F630	Format and punch a whole flie.
LOAD*	\$F69C	Load a whole file (if "FNCFL" $\neq 0$). Verify a whole file (if "FNCFL" = 0).

^{*}Tape routines have critically tuned execution times. Refer to detailed explanations.

7.4 Scratch RAM Descriptions

TABLE 7.2. SUMMARY OF MOST USED D5BUG SCRATCH RAM LOCATIONS (Also See Complete D5BUG Listing)

None of	(Also	See Complete D5BUG Listing)
Name of Routine	ADDR in D5BUG	Description
MNPTR	\$E419,A	Pointer to active sub-program.
KEY	\$E41B	Entered key code from keypad.
KYFLG	\$E41C	Flag to indicate a key is pending.
DISBUF	\$E41D-E422	(6) bytes correspond to (6) 7-segment displays. Contains 7-segment codes.
ROLPAS	\$E423	Flag to indicate first digit entry.
HEXBUF	\$E42C,D,E	3-byte buffer for hexadecimal information. Each byte corresponds to (2) 7-segment display digits.
USP	\$E42F,30	User stack pointer pseudo-register.
UCC	\$E431	User condition codes pseudo-register.
UB	\$E432	User B-register pseudo-register.
UA	\$E433	User A-register pseudo-register.
UX	\$E434,5	User X-register pseudo-register.
UPC	\$E436,7	User Program Counter pseudo-register.
UIRQV	\$E43C,D	Points to user's IRQ service routine.
FNCFL	\$E43E	Flag to indicate special (or alternate) function.
FNCPNT	\$E43F,40	Points to ADDR of user's special function table.
ВҮТЕ	\$E 4 59	Data byte read from cassette or to be punched to cassette.
BEGAD	\$E460,1	Beginning Address (for punch).
ENDAD	\$E462,3	Ending Address (for punch).

^{*}Tape routines have critically tuned execution times. Refer to detailed explanations.

7.5 Hardware Address Information

TABLE 7.3. USEFUL HARDWARE ADDRESS INFORMATION

Item	Description				
D5BUG ROM (U12)	\$F000 - F7FF but also "mirrors" such that contents shown in the listing as addresses (\$F400-F7FF) also appear at addresses (\$FC00-FFFF). This mapping is controlled by jumper arrangement J2.				
User ROM (U13)	ROM type controlled by J4 jumper arrangement (may be 1K x 8 or 2K x 8; single supply or triple supply; ROM or PROM) Mapping controlled by J3 jumper arrange ment may be mapped in any combination of the 1K address areas \$E800 - EBFF; \$EC00 - EFFF; \$F800 - FBFF; or \$FC00 - FFFF.				
System Scratch RAM	Located at \$E400 - E47F. This RAM is further divided into (3) sections: \$E400 - E418 provided for user's stack \$E419 - E463, D5BUG scratch RAM \$E464 - E47F, D5BUG stack				
User RAM (in U5)	\$0000 - 007F inside MC6802 (U5) available for user. Must be disabled by jumper E1 if expansion buffer (U3) is installed.				
Optional RAM (U7, U8)	\$E000 - E3FF optional MCM2114 RAMs available for user.				
System PİA	\$E484 - E487 which further breaks down to: \$E484 - Data Port A \$E485 - Control Reg A \$E486 - Data Port B \$E487 - Control Reg B				
	Also incomplete address decoding causes "mirroring" which makes this PIA also appear at addresses which meet this requirement: 1110 01XX 0XXX X0 XX 4 Regs in				
	where "X's" are don't care. The total number of "images" is (64) with the first image at \$E484 - E487 and the last image at \$E7F8 - E7FB.				

7.5 Hardware Address Information (cont'd)

TABLE 7.3. USEFUL HARDWARE ADDRESS INFORMATION (cont'd)

Item	Description
User PIA	\$E480 - E483 which further breaks down to: \$E480 - Data Port A \$E481 - Control Reg A \$E482 - Data Port B \$E483 - Control Reg B
	Also as with the system PIA above, incomplete Addr. decoding is responsible for "mirroring" at all addresses meeting the requirement: 1110 01XX 1XXX X1 XX or a total of (64) "images" with the first image at \$E480 - E483 and the last image at \$E7FC - E7FF.
ACIA (U33*) *Optional - not used when keypad is present	\$E700, E701 which further breaks down to: \$E700 Control/status register \$E701 Data register Also as with the PIA's above, incomplete address decoding is responsible for "mirroring" at all addresses meeting the requirement: 1110 0111 0XXX XXX X 2 REGS In ACIA or a total of (64) "images" with the first image at \$E700, E701 and the last image at \$E77E, E77F.
OFF-BOARD	\$0000 - \$DFFF, this 56K address area is assumed to be external to the MEK6802D5 for expansion purposes. To use this address space, install U1, U2, and U3 buffers and E1 (jumper to disable RAM in MC6802, U5).

7.6 D5BUG Listing

The following is the D5BUG Program Listing. It consists of 35 pages. Refer to paragraph 7.7 for a description of this listing.

7.7 D5BUG Listing Description

This description will be useful also for understanding other program listings in software.

Refer to page 001 RESET of the D5BUG. The left most five digits (or field) are called line number, shown under the PAGE heading. These numbers are used to keep track of the line number in the source code that a particular statement was on.

The letter appearing next to a line number (always A in the D5BUG)stands for ASCT, meaning "absolute section". This letter has meaning only when using a relocatable program.

The next four digits are ADDR, or address. This is the actual address in memory for the particular instruction. For instance, line 9 (00009A) has F000 which is a location in the D5BUG ROM. Successive addresses are not necessarily in progressive order.

The next digits are called OPCODE (one byte) for the instruction. For line 000099A, the OPCODE is 01.

The next digits or field can be zero bytes, one byte, or two bytes. At line $\emptyset\emptyset\emptyset\emptyset9A$, there are no bytes to the right of the OPCODE, but at line $\emptyset\emptyset\emptyset11A$, there are two bytes (E3 and FF), and at line $\emptyset\emptyset\emptyset13A$ there is one byte ($\emptyset\emptyset$). This general field is called the OPERAND.

At line $\emptyset\emptyset\emptyset\emptyset9A$, the notation NOP requires the OPERAND to be zero bytes. At line $\emptyset\emptyset\emptyset11A$, the notation LDX means OPCODE CE which requires the OPERAND to be two bytes which are E3 and FF. Thus, LDX is load x with E3 and FF as specified.

A special case of the OPERAND field is shown in line $\emptyset\emptyset\emptyset15A$. The OPCODE 26 is for BNE, which is "Branch Not Equal". The value F8 is the relative offset to CLRLOP. The F005 is a reference reminder that this is the "branch to" address.

In line $\emptyset\emptyset\emptyset12A$, the label CLRLOP is at address F $\emptyset\emptyset5$, so in line $\emptyset\emptyset\emptyset15A$, the "branch to" address is F $\emptyset\emptyset5$. In the ROM, the F005 is not present, but the notation 26 at F $\emptyset\emptysetB$ is present, along with F8 at F $\emptyset\emptysetC$.

At the next line, there is an FØØD and CE. Thus the FØØ5 is not a part of the code, but merely tells where to branch to.

The next field may contain a letter (A, shown in the D5BUG listing) which again is ASCT.

The next field is a label field but is not used very often. It is used as a reference reminder for the assembler.

7.7 D5BUG Listing Description (cont'd)

An asterisk (*) in the listing in the first column of any particular line of the source code, means that line is a comment. No code will be assigned by the assembler.

The mnemonic field (line $\emptyset\emptyset\emptyset\emptyset9A$ has NOP, no operation), is the English equivalent of the OPCODE.

The mnemonics are all listed in the Instruction Set Summary booklet for the M6800 microprocessor.

Also in this field are assembler directives, such as in line $\emptyset \emptyset \emptyset \emptyset 1$ - NAM, and OPT (option) in the next line. These do not generate any machine codes.

In line ØØØØ2, CREF and LLEN=80 stand for cross-reference and line length.

Another operand field is shown at line 90045A. The notation FOBB is the machine code operand and PUT is the source operand.

An operand can be a name, or a number as in line $\emptyset\emptyset\emptyset32$. LDAA #1 means "load A immediate one". The # symbol means "immediate". Also in this line ($\emptyset\emptyset\emptyset32A$), F $\emptyset27$ is the address in memory, 86 is the opcode for load A immediate, 01 is load with zero one.

In line $\emptyset\emptyset\emptyset38$, the symbol \$ means hex. In line $\emptyset\emptyset\emptyset4\emptyset$, the % symbol stands for binary. In line $\emptyset\emptyset\emptyset23$, 3, X specifies indexed addressing mode.

In line $\emptyset\emptyset\emptyset44$, the notation JSR ENNMI creates the code BD F7AE, which is explained by the comment "enable NMI" in the last field to the right.

At the end of the listing (after line 1333), another listing, the cross reference, is shown.

This starts with F789, an address for the label ABORT.

The line numbers (in the previous listing) for ABORT are 1198 and 120/2*. The number with the * is the line number where the label was defined, and the other number is the line where ABORT was used.

In this listing, line E442 is BKPNTR. It is referenced to ten places in the previous listing, and is defined in line 1286.

The cross reference listings (table) thus can be used to find any particular label in another listing.
